NASA Task Load Index (NASA-TLX) Version 1.0

Paper and Pencil Package

ooklet contains the materials necessary to collect subjective essments with the NASA Task Load Index. This procedure for rkload ratings was developed by the Human Performance Group nes Research Center during a three year research effort that technique is still undergoing evaluation, this booklet is being e than 40 laboratory. simulation. and inflight experiments. allow other researchers to use it in their own experiments. is intended to fill a 'nuts and bolts" function of describing the bibliography provides background information about previous suggestions about the procedure would be greatly appreciated. ngs and the logic that supports the procedure.

ONNO

SA Task Load Index is a multi-dimensional rating procedure ings on six subscales: Mental Demands, Physical Demands, Temporal that provides an overall workload score based on a weighted average of rat-Demands, Own Performance, Effort, and Frustration. A definition of each subscale is provided in Appendix A.

An earlier version of the scale had nine subscales. It was designed to subjects to weight and average subscale ratings. This technique (referred to as the "NASA Bipolar Rating Scale") was quite successful in reducing between rater variability, and it provided diagnostic information about the reduce between-rater variability by using the a priori workload definitions of magnitudes of different sources of load from subscale ratings (Hart, Battiste, & Lester, 1984; Vidulich & Tsang, 1985a & b). However, its sensitivity to experimental manipulations, while better than found for other popular techniques and for a global unidimensional workload rating, was still not considered sufficient. In addition, it was felt that nine subscales are too environment. Finally, several of the subscales were found to be irrelevant to many, making the scale impractical to use in a simulation or operational workload (e.g., Fatigue) or redundant (e.g., Stress and Frustration). For these reasons, the NASA Task Load Index was developed. Some of the subscales from the original scale were revised or combined, others deleted.

Sources-of-Workload Comparison Cards

The Task Load Index has been tested in a variety of experimental tasks that range from simulated flight to supervisory control simulations and laboratory tasks (e.g., the Sternberg memory task, choice reaction time, critical instability tracking, compensatory tracking, mental arithmetic, mental rotation, target acquisition, grammatical reasoning, etc.). The results of the first validation study are summarized in Hart & Staveland (in press). The derived workload scores have been found to have substantially less between-rater variability than unidimensional workload ratings, and the subscales provide diagnostic information about the sources of load.

2.2. Sources of Load (Weights)

The NASA Task Load Index is a two-part evaluation procedure consisting of both weights and ratings. The first requirement is for each rater specific task. These weights account for two potential sources of betweenrater variability: differences in workload definition between raters within a task, and differences in the sources of workload between tasks. In addition, the weights themselves provide diagnostic information about the nature of the workload imposed by the task.

There are 15 possible pair-wise comparisons of the six scales member of each pair is presented on a card. Subjects circle the The number of times that contributed more to the workload of that task. The number of times that each factor is selected is tallied. The tallies can range from 0 (not relevant) to 5 (more important than any other factor).

A different set of weights is obtained for each distinctly different task for many different upon its completion. The same set of weights can be used factors to their workload is fairly similar. For example, the same set of weights was used for many different versions of a target acquisition task in which time pressure, target acquisition difficulty, and decision making load lations increased the sensitivity of the derived workload score only slightly, and did not warrant the additional time required to gather them. On the tracking task or a memory search task would not have been appropriate for the target acquisition task

m

7. SUBJECT INSTRUCTIONS: SOURCES-OF-WORKLOAD

Throughout this experiment the rating scales are used to assess your experiences in the different task conditions. Scales of this sort are extremely useful, but their utility suffers from the tendency people have to interpret them in individual ways. For example, some people feel that mental or temporal demands are the essential aspects of workload regardless of the effort they expended on a given task or the level of performance they achieved. Others feel that if they performed well the workload must have been low and if they performed badly it must have been high. Yet others feel that effort or feelings of frustration are the most important factors in workload, and so on. The results of previous studies have already found every conceivable pattern of values. In addition, the factors that create levels of workload differ depending on the task. For example, some tasks might be difficult because they must be completed very quickly. Others may seem easy or hard because of the intensity of mental or physical effort required. Yet others feel difficult because they cannot be performed well, no matter how much effort is expended.

The evaluation you are about to perform is a technique that has been developed by NASA to assess the relative importance of six factors in determining how much workload you experienced. The procedure is simple: You will be presented with a series of pairs of rating scale titles (for example. Effort vs. Mental Demands) and asked to choose which of the items was more important to your experience of workload in the task(s) that you just performed. Each pair of scale titles will appear on a separate card.

Circle the Scale Title that represents the more important contributor to workload for the specific task(s) you performed in this experiment.

After you have finished the entire series we will be able to use the pattern of your choices to create a weighted combination of the ratings from that task into a summary workload score. Please consider your choices carefully and make them consistent with how you used the rating scales during the particular task you were asked to evaluate. Don't think that there is any correct pattern: we are only interested in your opinions.

If you have any questions, please ask them now. Otherwise, start whenever you are ready. Thank you for your participation.

the number of task conditions (including practice)

3.4. Weights

Subjects complete the 'Sources-of-Workload Evaluation" once for each task or group of tasks included in the experiment that share a common structure (although difficulty levels may vary). For example, in an experiment with several memory tasks and several tracking tasks, two Sources-of-Workload Evaluations would be performed: one for the memory tasks and one for the tracking tasks. One set of cards should be made in advance of the experiment for each subject X evaluation condition combination. The pairs of factors should be cut apart and presented individually in a different, randomly selected, order to each subject. Subject instructions for doing the Sources-of-Workload Evaluation are in Section 7. (Note that the exact time when the weights are obtained is not critical. However, in order for them to provide useful information, they must be obtained after at least some exposure to the relevant task conditions.)

3.5. Summary

Following this procedure, you should end up with: (1) a set of workload weights from each subject for each group of similar tasks, and (2) at least one rating sheet for each subject for each experimental task. Typically, we have run within subject experiments and therefore ended up with a larger number of rating sheets for each subject.

To conserve paper and speed up the subsequent analysis, we often enclose the Rating Sheet and the Sources-of-Workload comparison cards in clear plastic. Subjects mark the scales with an erasable felt tip marker. Immediately after they are marked, the experimenter transfers the responses onto the appropriate form or worksheet. Then the plastic sheets are cleaned and reused. If this procedure is followed, DOUBLE CHECK YOURSELF BEFORE ERASING THE SUBJECT'S RESPONSES!

4. DATA ANALYSIS PROCEDURE

The procedure for computing a weighted workload score follows:

1.1. Tally Sheet

For each subject, the "Sources-of-Workload Tally Sheet" (Appendix D) is used to compute the weight for each factor. The scorer simply leafs through the evaluation cards and puts a mark on the appropriate row of the tally column for each "Mental Demand" on a comparison card, the experimenter would put a mark in the "Mental Demand" row of the tally column). After going through the Sources-of-Workload evaluation, the in the "Weight" column.

1.2. Worksheet

The Weight column from the tally sheet is then transferred to the "Weighted Rating Worksheet" (Appendix E). Each subject would have his or her individual workload parameters count placed on a separate worksheet for the appropriate task or set of similar tasks. If subjects rated more than one task the appropriate number of copies of the worksheet should be made. The "Adjusted Rating" is formed by multiplying the Raw Rating by the Sources-of-Workload Weight. The adjusted ratings are to obtain the overall weighted workload score for the subject in that one task condition.

The weighted ratings are then used as a dependent measure in what-ever type of analyses the experimenter chooses.

Figure 1 depicts the composition of a weighted workload score graphically. The bar graph on the left represents six subscale ratings. The width of the subscale bars reflects the importance of each factor (its weight) and the height represents the magnitude of each factor (its rating) in a particular average area of the subscale bars.

1.3. Summary

The above procedure, although simple, can be laborious for a large experiment. Thus it is highly advantageous to computerize the procedure. A set of programs that run on IBM-PC compatible machines has been

SUBJECT INSTRUCTIONS: RATING SCALES

We are not only interested in assessing your performance but also the going to describe the technique that will be used to examine your experiences. In the most general sense we are examining the "workload" you one to understand generally. The factors that influence your experienced. Workload is a difficult concept to define precisely, but a simple workload may come from the task itself, your feelings about your own performance, how much effort you put in, or the stress and frustration you felt, more familiar with a task. perform easier or harder versions of it, or move easy to conceptualize and evaluate. However, the mental components of workload may be more difficult to measure.

Since workload is something that is experienced individually by each load of different activities. One way to find out about workload is to ask people to describe the feelings they experienced. Because workload may be them individually rather than lumping them into a single global evaluation of overall workload. This set of six rating scales was developed for you to use descriptions of the scales carefully. If you have a question about any of the scales in the table, please ask me about it. It is extremely important that during the experiment

After performing each of the tasks, you will be given a sheet of rating at the point which matches your experience. Each line has two endpoint descriptors that describe the scale. Note that 'own performance' goes from some people. Please consider your responses carefully in distinguishing among the different task conditions. Consider each scale individually. Your your active participation is essential to the success of this experiment and is greatly appreciated by all of us.

2.3. Magnitude of Load (Ratings)

The second requirement is to obtain numerical ratings for each scale presented on a rating sheet (Appendix C). Subjects respond by marking verbal responses are more practical, while a computerized version (available and laboratory settings. Ratings may be obtained either during a task, after 12-cm line divided into 20 equal intervals anchored by bipolar descriptors from 0 to 100 in increments of 5. If a subject marks between two ticks, the value of the right tick is used (i.e., round up).

2.4. Weighting and Averaging Procedure

The overall workload score for each subject is computed by multiplying each rating by the weight given to that factor by that subject. The sum of the weighted ratings for each task is divided by 15 (the sum of the weights). (See Appendix D and E for a sample Tally Sheet and Worksheet.)

3. EXPERIMENTAL PROCEDURE

The usual sequence of events for collecting data with the NASA Task Load Index is as follows:

3.1. Instructions

Subjects read the scale definitions and instructions. A set of generic instructions is included in Section 6. Some modifications may be necessary depending on your situation.

3.2. Familiarization

Subjects practice using the rating scales after performing a few tasks to insure that they have developed a standard technique for dealing with the scales.

3.3. Ratings

Subjects perform the experimental tasks, providing ratings on the six subscales following all task conditions of interest. The number of rating sheets needed equals the number of subjects X

Appendix A.

	RATING SO	RATING SCALE DEFINITIONS

CHIMAINCE	8ood/boor	How successful do you think you were in accomplishing the goals of the task set by the experimenter (or yourself)? How satisfied were you with your performance in accomplishing these goals?
EFFORT	Low/High	How hard did you have to work (mentally and physically) to accomplish your level of performance?
FRUSTRATION LEVEL	Low/High	How insecure, discouraged, irritated, stressed and annoyed versus secure, gratified, content, relaxed and complacent did you feel during the task?

and two added. Three dimensions relate to the demands imposed on the subject (Mental, Physical, and Temporal Demands) and three to the interaction of a subject with the task (Effort, Frustration, and Performance).

Temporal Demand

Effort

Although it is clear that definitions of workload do indeed vary among load literature and among subjects (contributing to confusion in the work-sources of loading imposed by different tasks are an even more important determinant of workload experiences. Thus, the current version of the scale (the Task Load Index) combines subscale ratings that are weighted according to their subjective importance to raters in a specific task, rather than their a priori relevance to raters definitions of workload in general.

2. DESCRIPTION

2.1. General Information

The degree to which each of the six factors contribute to the workload of the specific task to be evaluated, from the raters perspectives, is determined by their responses to pair-wise comparisons among the six factors. Magnitude ratings on each subscale are obtained after each performance of a task or task segment. Ratings of factors deemed most important in creating the workload of a task are given more weight in computing the overall workload score, thereby enhancing the sensitivity of the scale.

The weights and ratings may or may not covary. For example, it is possible for mental demands to be the primary source of loading for a task, even though the magnitude of the mental demands might be low. Conversely, the time pressure under which a task is performed might be the primary source of its workload, and the time demands might be rated as being high for some versions of the task and low for others.

Since subjects can give ratings quickly, it may be possible to obtain regenerational settings. However, a videotaped replay or computer that can be stopped after each segment to obtain ratings retospectively. It (Hart, Battiste, Chesney, Ward, & McElroy, 1986; Haworth, Bivens, and Shively, 1986) that little information was lost when ratings were given obtained 'tonline" and those that were obtained retrospectively with a visual
